Chapter 2
Structured Web Documents in XML

Adapted from slides from Grigoris Antoniou and Frank van Harmelen
Outline

(1) Introduction
(2) XML details
(3) Structuring
  - DTDs
  - XML Schema
(4) Namespaces
(5) Accessing, querying XML documents: XPath
(6) Transformations: XSLT
Most of the Semantic Web involves ideas and languages at a fairly abstract level, e.g., for defining ontologies, publishing data using them. But we also need a practical way of encoding the abstract languages. Today’s Web technology is (still) heavily based on XML standards. So XML is (1) the source for many key SW concepts technology bits; (2) a potential alternative the SW must improve on; and (3) a common serialization for SW data.
To paraphrase Jamie Zawinski

Some people, when confronted with a problem, think, "I know, I'll use XML."

Now they have two problems.

“Some people, when confronted with a problem, think "I know, I'll use regular expressions." Now they have two problems.”

-- Wikiquote
XML’s roots are in SGML
- Standard Generalized Markup Language
- A *metalanguage* for defining document markup languages
- Very extensible, but very complicated

HTML was defined using SGML
- It’s a markup language, not a *markup metalanguage*

XML proposal to W3C in July 1996
- Idea: a simplified SGML could greatly expand the power and flexibility of the Web
- First XML Meeting, August 1996, Seattle

Evolving series of W3C recommendations
Nonmonotonic Reasoning: Context-Dependent Reasoning
by V. Marek and M. Truszczynski
Springer 1993
ISBN 0387976892
<book>
  <title>Nonmonotonic Reasoning: Context-Dependent Reasoning</title>
  <author>V. Marek</author>
  <author>M. Truszczynski</author>
  <publisher>Springer</publisher>
  <year>1993</year>
</book>
Both use **tags** (e.g. `<h2>` and `</year>`)  
- Tags may be nested (tags within tags)  
- Human users can read and interpret both HTML and XML representations quite easily  

... But how about machines?
Problems Interpreting HTML Documents

An intelligent agent trying to retrieve the names of the authors of the book

- Authors’ names could appear immediately after the title
- or immediately after the word “by” or “van” if it’s in Dutch
- Are there two authors?
- Or just one, called “V. Marek and M. Truszczynski”?
HTML vs XML: Structural Information

- HTML documents do not contain structural information: pieces of the document and their relationships.
- XML more easily accessible to machines because:
  - Every piece of information is described
  - Relations are also defined through the nesting structure
  - E.g., `<author>` tags appear within the `<book>` tags, so they describe properties of the particular book
A machine processing the XML document would be able to deduce that
- the **author** element refers to the enclosing **book** element
- rather than by proximity considerations or other heuristics

XML allows the definition of constraints on values
- E.g. a year must be a number of four digits

(1) Introduction
HTML vs. XML: Formatting

- The HTML representation provides more than the XML representation:
  - Formatting of the document is also described
- The main use of an HTML document is to display information: it must define formatting
- **XML: separation of content from display**
  - same information can be displayed in different ways
  - Presentation specified by documents using other XML standards (CSS, XSL)
HTML vs. XML: Another Example

In HTML

<h2>Relationship matter-energy</h2>
<i> E = M × c2 </i>

In XML

<equation>
   <gloss>Relationship matter energy </gloss>
   <leftside> E </leftside>
   <rightside> M × c2 </rightside>
</equation>

(1) Introduction
HTML vs. XML: Different Use of Tags

- Both HTML documents use the same tags
- The XML documents use completely different tags
- HTML tags come from and finite, pre-defined collection
- They define properties for display: font, color, lists …
- XML tags not fixed: user definable tags
- XML meta markup language: language for defining markup languages
XML Vocabularies

- Web applications must agree on common vocabularies to communicate and collaborate
- Communities and business sectors define their specialized vocabularies
  - mathematics (MathML)
  - bioinformatics (BSML)
  - human resources (HRML)
  - Syndication (RSS)
  - Vector graphics (SVG)
  - ...

(1) Introduction
Outline

1. Introduction
2. Detailed Description of XML
   - DTDs
   - XML Schema
3. Structuring
4. Namespaces
5. Accessing, querying XML documents: XPath
6. Transformations: XSLT
An XML document consists of

- a prolog
- a number of elements
- an optional epilog (not discussed, not used much)
The prolog consists of

- an XML declaration and
- an optional reference to external structuring documents

```xml
<?xml version="1.0" encoding="UTF-16"?>

<!DOCTYPE book SYSTEM "book.dtd">"
XML Elements

- Elements are the “things” the XML document talks about
  - E.g., books, authors, publishers

- An element consists of:
  - an opening tag
  - the content
  - a closing tag

<lecturer> David Billington </lecturer>
Tag names can be chosen almost freely.
The first character must be a letter, an underscore, or a colon.
No name may begin with the string “xml” in any combination of cases
  - E.g. “Xml”, “xML”
Content of XML Elements

- Content is what’s between the tags
- It can be text, or other elements, or nothing

  <lecturer>
    <name>David Billington</name>
    <phone> +61 − 7 − 3875 507 </phone>
  </lecturer>

- If there is no content, then the element is called empty; it can be abbreviated as follows:

  <lecturer/>  =  <lecturer></lecturer>
XML Attributes

- An empty element is not necessarily meaningless
  - It may have properties expressed as attributes
- An **attribute** is a name-value pair inside the opening tag of an element

```xml
<lecturer
  name="David Billington"
  phone="+61 − 7 − 3875 507" />
```
<order orderNo="23456"
customer="John Smith"
date="October 15, 2002" >
  <item itemNo="a528" quantity="1" />
  <item itemNo="c817" quantity="3" />
</order>
The Same Example without Attributes

<order>
  <orderNo>23456</orderNo>
  <customer>John Smith</customer>
  <date>October 15, 2002</date>
  <item>
    <itemNo>a528</itemNo>
    <quantity>1</quantity>
  </item>
  <item>
    <itemNo>c817</itemNo>
    <quantity>3</quantity>
  </item>
</order>

(2) XML details
XML Elements vs. Attributes

- Attributes can be replaced by elements
- When to use elements and when attributes is a matter of taste
- But attributes **cannot** be nested
Further Components of XML Docs

- **Comments**
  - A piece of text that is to be ignored by parser
  ```xml
  <!-- This is a comment -->
  ```

- **Processing Instructions (PIs)**
  - Define procedural attachments
  ```xml
  <?stylesheet type="text/css" href="mystyle.css"?>
  ```
Well-Formed XML Documents

Syntactically correct documents must adhere to many rules

- Only one outermost element (the root element)
- Each element contains an opening and a corresponding closing tag
- Tags may not overlap
  
  <author><name>Lee Hong</name></author>

- Attributes within an element have unique names
- Element and tag names must be permissible
The tree representation of an XML document is an ordered labeled tree:

- There is exactly one root
- There are no cycles
- Each non-root node has exactly one parent
- Each node has a label.
- The order of elements is important
- … but the order of attributes is not important
<email>
  <head>

(email, body: Grigoris, where is the draft of the paper you promised me last week?)

(root)
Outline

1. Introduction
2. Detailed Description of XML
3. Structuring
   - DTDs
   - XML Schema
4. Namespaces
5. Accessing, querying XML documents: XPath
6. Transformations: XSLT
Some XML documents are required to follow constraints defined in a “template” that can…

- define all the *element* and *attribute names* that may be used
- define the *structure*
  - what values an attribute may take
  - which elements may or must occur within other elements, etc.

If such structuring information exists, the document can be *validated*
An XML document is **valid** if
- it is well-formed
- respects the structuring information it uses

Ways to define the structure of XML documents:
- **DTDs** (*Document Type Definition*) came first, was based on SGML’s approach.
- **XML Schema** (aka *XML Schema Definition*, XSD) is more recent and expressive
- **RELAX NG** and **DSDs** are two alternatives
DTD: Element Type Definition

<lecturer>
  <name>David Billington</name>
  <phone> +61 − 7 − 3875 507 </phone>
</lecturer>

DTD for above element (and all lecturer elements):

<!ELEMENT lecturer (name, phone) >
<!ELEMENT name (#PCDATA) >
<!ELEMENT phone (#PCDATA) >

(3) Structure: DTDs
The element types **lecturer**, **name**, and **phone** may be used in the document.

- A **lecturer** element contains a **name** element and a **phone** element, in that order (*sequence*).
- A **name** element and a **phone** element may have any content.
  - In DTDs, **#PCDATA** is the only atomic type for elements.
  - **PCDATA** = “*parsed character data*”
We express that a **lecturer** element contains *either* a **name** element *or* a **phone** element as follows:

```xml
<!ELEMENT lecturer ( name | phone )>
```

A **lecturer** element contains a **name** element and a **phone** element in *any order*.

```xml
<!ELEMENT lecturer((name,phone)|(phone,name))>
```

Do you see a problem with this approach?
Example of an XML Element

<order orderNo="23456"
    customer="John Smith"
    date="October 15, 2002">
    <item itemNo="a528" quantity="1" />
    <item itemNo="c817" quantity="3" />
</order>
<ELEMENT order (item+)>  
<!ATTLIST order      
   orderNo   ID   #REQUIRED   
   customer  CDATA  #REQUIRED   
   date      CDATA  #REQUIRED >  

<ELEMENT item EMPTY>  
<!ATTLIST item        
   itemNo   ID   #REQUIRED   
   quantity CDATA  #REQUIRED   
   comments CDATA  #IMPLIED >
The `item` element type is defined to be empty – i.e., it can contain no elements.

- `+` (after `item`) is a **cardinality operator**:
  - Specifies how many `item` elements can be in an order
  - `?`: appears zero times or once
  - `*`: appears zero or more times
  - `+`: appears one or more times
- No cardinality operator means exactly once
In addition to defining elements, we define attributes

This is done in an attribute list containing:
- Name of the element type to which the list applies
- A list of triplets of attribute name, attribute type, and value type

Attribute name: A name that may be used in an XML document using a DTD
Similar to predefined data types, but limited selection

The most important types are
- **CDATA**, a string (sequence of characters)
- **ID**, a name that is *unique* across the entire XML document (~ DB key)
- **IDREF**, a reference to another element with an ID attribute carrying the same value as the IDREF attribute (~ DB foreign key)
- **IDREFS**, a series of IDREFs
- **(v1| . . . |vn)**, an enumeration of all possible values

Limitations: no dates, number ranges etc.
DTD: Attribute Value Types

- **#REQUIRED**
  - Attribute must appear in every occurrence of the element type in the XML document

- **#IMPLIED**
  - The appearance of the attribute is optional

- **#FIXED "value"**
  - Every element must have this attribute

- **"value"**
  - This specifies the default value for the attribute
Referencing with IDREF and IDREFS

<!ELEMENT family (person*)>
<!ELEMENT person (name)>
<!ELEMENT name (#PCDATA)>
<!ATTLIST person
  id ID #REQUIRED
  mother IDREF #IMPLIED
  father IDREF #IMPLIED
  children IDREFS #IMPLIED >

(3) Structure: DTDs
An XML Document Respecting the DTD

```
<family>
    <person id="bob" mother="mary" father="peter">
        <name>Bob Marley</name>
    </person>
    <person id="bridget" mother="mary">
        <name>Bridget Jones</name>
    </person>
    <person id="mary" children="bob bridget">
        <name>Mary Poppins</name>
    </person>
    <person id="peter" children="bob">
        <name>Peter Marley</name>
    </person>
</family>
```
A DTD for an Email Element

<!ELEMENT email (head, body)>
<!ELEMENT head (from, to+, cc*, subject)>
<!ELEMENT from EMPTY>
<!ATTLIST from>
  name CDATA  #IMPLIED
  address CDATA  #REQUIRED>
<!ELEMENT to EMPTY>
<!ATTLIST to>
  name CDATA  #IMPLIED
  address CDATA  #REQUIRED>
A DTD for an Email Element

<!ELEMENT cc EMPTY>
<!ATTLIST cc
  name      CDATA     #IMPLIED
  address   CDATA     #REQUIRED>
<!ELEMENT subject (#PCDATA) >
<!ELEMENT body (text,attachment*) >
<!ELEMENT text (#PCDATA) >
<!ELEMENT attachment EMPTY >
<!ATTLIST attachment
  encoding   (mime|binhex)    "mime"
  file       CDATA     #REQUIRED>

(3) Structure: DTDs
Interesting Parts of the DTD

- A **head** element contains (in order):
  - a **from** element
  - at least one **to** element
  - zero or more **cc** elements
  - a **subject** element

- In **from**, **to**, and **cc** elements
  - the **name** attribute is not required
  - the **address** attribute is always required
Interesting Parts of the DTD

- A **body** element contains
  - a **text** element
  - possibly followed by a number of **attachment** elements
- The **encoding** attribute of an **attachment** element must have either the value “**mime**” or “**binhex**”
  - “**mime**” is the default value
Remarks on DTDs

- A DTD can be interpreted as an Extended Backus-Naur Form (EBNF)
  - `<!ELEMENT email (head, body)>`
  - is equivalent to `email ::= head body`
- Recursive definitions possible in DTDs
  - `<!ELEMENT bintree ((bintree root bintree)|emptytree)>`
(1) Introduction
(2) Detailed Description of XML
(3) Structuring
   - DTDs
   - XML Schema
(4) Namespaces
(5) Accessing, querying XML documents: XPath
(6) Transformations: XSLT
XML Schema

- XML Schema is a significantly richer language for defining the structure of XML documents.
- Syntax is based on XML itself => separate tools to handle them not needed.
- Reuse and refinement of schemas => can expand or delete existing schemas.
- Sophisticated set of data types, compared to DTDs (which only supports strings).
An XML schema is an element with an opening tag like

```xml
<schema
    "http://www.w3.org/2000/10/XMLSchema"
    version="1.0">
```

Structure of schema elements
- Element and attribute types using data types
Element Types

```xml
<element name="email"/>
<element name="head"
    minOccurs="1"
    maxOccurs="1"/>
<element name="to" minOccurs="1"/>
```

Cardinality constraints:
- `minOccurs="x"` (default value 1)
- `maxOccurs="x"` (default value 1)
- Generalizations of *, ?, + offered by DTDs

(3) Structure: XML Schema
Attribute Types

```xml
<attribute name="id" type="ID" use="required"/>
<attribute name="speaks" type="Language" use="default" value="en"/>
```

- Existence: `use="x"`, where x may be optional or required
- Default value: `use="x" value="..."`, where x may be default or fixed
There are many built-in data types

- Numerical data types: integer, Short etc.
- String types: string, ID, IDREF, CDATA etc.
- Date and time data types: time, Month etc.

There are also user-defined data types

- simple data types, which can’t use elements or attributes
- complex data types, which can use these
Complex data types are defined from existing data types by defining some attributes (if any) and using:

- **sequence**, a sequence of existing data type elements (order is important)
- **all**, a collection of elements that must appear (order is not important)
- **choice**, a collection of elements, of which one will be chosen
A Data Type Example

<complexType name="lecturerType">
  <sequence>
    <element name="firstname" type="string"
             minOccurs="0" maxOccurs="unbounded"/>
    <element name="lastname" type="string"/>
  </sequence>
  <attribute name="title" type="string"
             use="optional"/>
</complexType>

(3) Structure: XML Schema
Already existing data types can be extended by new elements or attributes. Example:

```xml
<complexType name="extendedLecturerType">
    <extension base="lecturerType">
        <sequence>
            <element name="email" type="string"
                minOccurs="0" maxOccurs="1"/>
        </sequence>
        <attribute name="rank" type="string"
            use="required"/>
    </extension>
</complexType>
```
<complexType name="extendedLecturerType">
  <sequence>
    <element name="firstname" type="string"
             minOccurs="0" maxOccurs="unbounded"/>
    <element name="lastname" type="string"/>
    <element name="email" type="string"
             minOccurs="0" maxOccurs="1"/>
  </sequence>
  <attribute name="title" type="string" use="optional"/>
  <attribute name="rank" type="string" use="required"/>
</complexType>
Data Type Extension

A **hierarchical relationship** exists between the original and the extended type

- Instances of the extended type are also instances of the original type
- They may contain additional information, but neither less information, nor information of the wrong type
Data Type Restriction

- An existing data type may be restricted by adding constraints on certain values
- Restriction is not the opposite from extension
  - Restriction is not achieved by deleting elements or attributes
- The following **hierarchical relationship** still holds:
  - Instances of the restricted type are also instances of the original type
  - They satisfy at least the constraints of the original type
Example of Data Type Restriction

```xml
<complexType name="restrictedLecturerType">
    <restriction base="lecturerType">
        <sequence>
            <element name="firstname" type="string"
                minOccurs="1" maxOccurs="2"/>
        </sequence>
        <attribute name="title" type="string"
            use="required"/>
    </restriction>
</complexType>
```
<simpleType name="dayOfMonth">
  <restriction base="integer">
    <minInclusive value="1"/>
    <maxInclusive value="31"/>
  </restriction>
</simpleType>
Data Type Restriction: Enumeration

```xml
<simpleType name="dayOfWeek">
    <restriction base="string">
        <enumeration value="Mon"/>
        <enumeration value="Tue"/>
        <enumeration value="Wed"/>
        <enumeration value="Thu"/>
        <enumeration value="Fri"/>
        <enumeration value="Sat"/>
        <enumeration value="Sun"/>
    </restriction>
</simpleType>
```
<element name="email" type="emailType"/>

<complexType name="emailType">
  <sequence>
    <element name="head" type="headType"/>
    <element name="body" type="bodyType"/>
  </sequence>
</complexType>
<complexType name="headType">
    <sequence>
        <element name="from" type="nameAddress"/>
        <element name="to" type="nameAddress" minOccurs="1" maxOccurs="unbounded"/>
        <element name="cc" type="nameAddress" minOccurs="0" maxOccurs="unbounded"/>
        <element name="subject" type="string"/>
    </sequence>
</complexType>
XML Schema: The Email Example

<complexType name="nameAddress">
    <attribute name="name" type="string" use="optional"/>
    <attribute name="address" type="string" use="required"/>
</complexType>

● Similar for bodyType
Outline

(1) Introduction
(2) Detailed Description of XML
(3) Structuring
  - DTDs
  - XML Schema
(4) Namespaces
(5) Accessing, querying XML documents: XPath
(6) Transformations: XSLT
Namespaces

- An XML document may use more than one DTD or schema
- Since each structuring document was developed independently, name clashes may appear
- The solution is to use a different prefix for each DTD or schema
  - `prefix:name`
- Namespaces are even more important in RDF
<vu:instructors xmlns:vu="http://www.vu.com/empDTD"
       xmlns:gu="http://www.gu.au/empDTD"
       xmlns:uky="http://www.uky.edu/empDTD">
<uky:faculty uky:title="assistant professor"
     uky:name="John Smith"
     uky:department="Computer Science"/>
<gu:academicStaff gu:title="lecturer"
     gu:name="Mate Jones"
     gu:school="Information Technology"/>
</vu:instructors>
Namespaces are declared within an element and can be used in that element and any of its children (elements and attributes).

A namespace declaration has the form:

- `xmlns:prefix="location"`
- `location` is the address of the DTD or schema

If a prefix is not specified: `xmlns="location"` then the `location` is used as the `default` prefix.
Outline

(1) Introduction
(2) Detailed Description of XML
(3) Structuring
  - DTDs
  - XML Schema
(4) Namespaces
(5) Accessing, querying XML docs: XPath
(6) Transformations: XSLT
Addressing & Querying XML Documents

- In relational databases, parts of a database can be selected and retrieved using SQL
  - Also very useful for XML documents
  - **Query languages**: XQuery, XQL, XML-QL
- The central concept of XML query languages is a path expression
  - Specifies how a node or a set of nodes, in the tree representation of the XML document can be reached
XPath

- **XPath** is core for XML query languages
- Language for addressing parts of an XML document.
  - It operates on the tree data model of XML
  - It has a non-XML syntax
- Two versions
  - **XPath 1.0** (1999) is widely supported
  - **XPath 2.0** (2007) is a more expressive subset of Xquery and not as widely supported
Types of Path Expressions

- **Absolute** (starting at the root of the tree)
  - Syntactically they begin with the symbol `/`
  - It refers to the root of the document (situated one level above the root element of the document)

- **Relative** to a context node
An XML Example

<library location="Bremen">
  <author name="Henry Wise">
    <book title="Artificial Intelligence"/>
    <book title="Modern Web Services"/>
    <book title="Theory of Computation"/>
  </author>
  <author name="William Smart">
    <book title="Artificial Intelligence"/>
  </author>
  <author name="Cynthia Singleton">
    <book title="The Semantic Web"/>
    <book title="Browser Technology Revised"/>
  </author>
</library>
Examples of Path Expressions in XPath

- **Q1: /library/author**
  - Addresses all *author* elements that are children of the *library* element node immediately below the root
  - */t1/.../tn*, where each $t_{i+1}$ is a child node of $t_i$, is a path through the tree representation

- **Q2: //author**
  - Here // says that we should consider all elements in the document and check whether they are of type *author*
  - This path expression addresses all *author* elements anywhere in the document
Examples of Path Expressions in XPath

- **Q3: /library/@location**
  - Addresses the location attribute nodes within library element nodes
  - The symbol `@` is used to denote attribute nodes

- **Q4: //book/@title="Artificial Intelligence"**
  - Addresses all title attribute nodes within book elements anywhere in the document, which have the value “Artificial Intelligence”
Tree Representation of Query 4
Examples of Path Expressions in XPath

- **Q5: /book[@title="Artificial Intelligence"]**
  - Addresses all books with title “Artificial Intelligence”
  - A test in brackets is a **filter expression** that restricts the set of addressed nodes.
  - Note differences between Q4 and Q5:
    - Query 5 addresses `book` elements, the `title` of which satisfies a certain condition.
    - Query 4 collects `title` attribute nodes of `book` elements.
Tree Representation of Query 5

(5) XPath
Examples of Path Expressions in XPath

- **Q6**: Address first author element node in the XML document
  
  ```
  //author[1]
  ```

- **Q7**: Address last book element within the first author element node in the document
  
  ```
  //author[1]/book[last()]
  ```

- **Q8**: Address all book element nodes without a title attribute
  
  ```
  //book[not (@title)]
  ```
General Form of Path Expressions

- A **path expression** consists of a series of steps, separated by slashes.

- A **step** consists of:
  - An axis specifier,
  - A node test, and
  - An optional **predicate**.
General Form of Path Expressions

- An **axis specifier** determines the tree relationship between the nodes to be addressed and the context node
  - E.g. parent, ancestor, child (the default), sibling, attribute node
  - // is such an axis specifier: descendant or self

(5) XPath
General Form of Path Expressions

- A **node test** specifies which nodes to address
  - The most common node tests are element names
  - E.g., * addresses all element nodes
  - `comment()` addresses all comment nodes
General Form of Path Expressions

- **Predicates** (or *filter expressions*) are optional and are used to refine the set of addressed nodes.
  - E.g., the expression `[1]` selects the first node.
  - `[position()=last()]` selects the last node.
  - `[position() mod 2 =0]` selects the even nodes.

- XPath has a more complicated full syntax.
  - We have only presented the abbreviated syntax.
(1) Introduction
(2) Detailed Description of XML
(3) Structuring
  – DTDs
  – XML Schema
(4) Namespaces
(5) Accessing, querying XML documents: XPath
(6) Transformations: XSLT
Idea: use an external style sheet to transform an XML tree into an HTML or XML tree
Style Sheets

- Style sheets can be written in various languages
  - E.g. CSS2 (cascading style sheets level 2)
  - XSL (extensible stylesheet language)

- XSL includes
  - a transformation language (XSLT)
  - a formatting language
  - Both are XML applications
XSLT specifies rules with which an input XML document is transformed to
- another XML document
- an HTML document
- plain text

The output document may use the same DTD or schema, or a completely different vocabulary

XSLT can be used independently of the formatting language

(5) XSLT transformations
XSLT

- Move data and metadata from one XML representation to another
- XSLT is chosen when applications that use different DTDs or schemas need to communicate
- XSLT can be used for machine processing of content without any regard to displaying the information for people to read.
- In the following example we use XSLT only to display XML documents as HTML

```xml
<?xml version="1.0"
<xsl:stylesheet xmlns:xsl
<!-- created 2005-12-12-->
<xsl:include href="xslt" xmlns:xsl="http://www.w3.org/1999/XSL/Transform" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
<xsl:template match="/">
  <root>
    <!-- Heuristic: <xsl:value-of
    <p>The leading manufac</p>
  </root>
</xsl:template>
</xsl:stylesheet>
```
<xsl:template match="/author">
  <html>
    <head><title>An author</title></head>
    <body bgcolor="white">
      <b><xsl:value-of select="name"/></b><br>
      <xsl:value-of select="affiliation"/><br>
      <i><xsl:value-of select="email"/></i>
    </body>
  </html>
</xsl:template>

(5) XSLT transformations
<author>
  <name>Grigoris Antoniou</name>
  <affiliation>University of Bremen</affiliation>
  <email>ga@tzi.de</email>
</author>

<xsl:template match="/author"> 
  <html>
    <head><title>An author</title></head>
    <body bgcolor="white">
      <b><xsl:value-of select="name"/></b><br>
      <xsl:value-of select="affiliation"/><br>
      <i><xsl:value-of select="email"/></i>
    </body>
  </html>
</xsl:template>

<html>
  <head><title>An author</title></head>
  <body bgcolor="white">
    <b>Grigoris Antoniou</b><br>
    University of Bremen<br>
    <i>ga@tzi.de</i>
  </body>
</html>
Observations About XSLT

- XSLT documents are XML documents
  - XSLT resides on top of XML
- The XSLT document defines a template
  - In this case an HTML document, with some placeholders for content to be inserted
- `xsl:value-of` retrieves the value of an element and copies it into the output document
  - It places some content into the template
A Template

<html>
<head><title>An author</title></head>
<body bgcolor="white">
  <b>...</b><br>
  ...<br>
  ...<br>
  <i>...</i><br>
</body>
</html>
Auxiliary Templates

- We have an XML document with details of several authors.
- It is a waste of effort to treat each author element separately.
- In such cases, a special template is defined for author elements, which is used by the main template.
Example of an Auxiliary Template

<authors>
  <author>
    <name>Grigoris Antoniou</name>
    <affiliation>University of Bremen</affiliation>
    <email>ga@tzi.de</email>
  </author>
  <author>
    <name>David Billington</name>
    <affiliation>Griffith University</affiliation>
    <email>david@gu.edu.net</email>
  </author>
</authors>

(5) XSLT transformations
Example of an Auxiliary Template (2)

```xml
<xsl:template match="/">
  <html>
    <head><title>Authors</title></head>
    <body bgcolor="white">
      <xsl:apply-templates select="author"/>
      <!-- apply templates for AUTHORS children -->
    </body>
  </html>
</xsl:template>
```

(5) XSLT transformations
Example of an Auxiliary Template (3)

<xsl:template match="authors">
    <xsl:apply-templates select="author"/>
</xsl:template>

<xsl:template match="author">
    <h2><xsl:value-of select="name"/></h2>
    <p> Affiliation:<xsl:value-of select="affiliation"/><br/>
    Email: <xsl:value-of select="email"/> </p>
</xsl:template>
<html>
<head><title>Authors</title></head>
<body bgcolor="white">
  <h2>Grigoris Antoniou</h2>
  <p>Affiliation: University of Bremen<br/>
  Email: ga@tzi.de</p>
  <h2>David Billington</h2>
  <p>Affiliation: Griffith University<br/>
  Email: david@gu.edu.net</p>
</body>
</html>
Explanation of the Example

**xsl:apply-templates** element causes all children of the context node to be matched against the selected path expression

- e.g., if current template applies to /, then element **xsl:apply-templates** applies to root element
- i.e., the **authors** element (/ is located above root)
- If current context node is the **authors** element, then element **xsl:apply-templates select="author"** causes the template for the **author** elements to be applied to all **author** children of the **authors** element

(5) XSLT transformations
Explanation of the Example

- It is good practice to define a template for each element type in the document
  - Even if no specific processing is applied to certain elements, the `xsl:apply-templates` element should be used
  - E.g. `authors`  

- In this way, we work from the root to the leaves of the tree, and all templates are applied
Suppose we wish to transform to itself the element:

```xml
<person firstname="John" lastname="Woo"/>
```

Wrong solution:

```xml
<xsl:template match="person">
    <person firstname=""<xsl:value-of select="/@firstname">"">
        lastname=""<xsl:value-of select="/@lastname">"/>
    </person>
</xsl:template>
```
Processing XML Attributes

- Not well-formed because tags are not allowed within the values of attributes
- We wish to add attribute values into template

```xml
<xsl:template match="person">
  <person
      firstname="{@firstname}"
      lastname="{@lastname}" />
</xsl:template>
```
Transforming an XML Document to Another

(5) XSLT transformations
Transforming an XML Document to Another

```xml
<xsl:template match="/">
  <?xml version="1.0" encoding="UTF-16"?>
  <authors>
    <xsl:apply-templates select="authors"/>
  </authors>
</xsl:template>

<xsl:template match="authors">
  <author>
    <xsl:apply-templates select="author"/>
  </author>
</xsl:template>
```

(5) XSLT transformations
<xsl:template match="author">
  <name><xsl:value-of select="name"/></name>
  <contact>
    <institution>
      <xsl:value-of select="affiliation"/>
    </institution>
    <email><xsl:value-of select="email"/></email>
  </contact>
</xsl:template>
Applying XSLT

- When a modern browser loads an XML file, it will apply a linked XSLT and display the results (hopefully HTML!)
- Use an external Web service
- Use an XML editor
- Use a module or library for your favorite programming language
An XSLT Web Service

CD Catalog example

<?xml-stylesheet type="text/xsl" href="cdcatalog.xsl" ?>
<catalog>
<cd>
  <title>Empire Burlesque</title>
  <artist>Bob Dylan</artist>
  <country>USA</country>
  <company>Columbia</company>
  <price>10.90</price>
  <year>1985</year>
</cd>
<cd>
  <title>Hide your heart</title>
  <artist>Bonnie Tyler</artist>
  <country>UK</country>
  <company>CBS Records</company>
  ...
</cd> ...

<xsl:template match="/">
<html> <body>
<h2>My CD Collection</h2>
<table border="1">
<tr bgcolor="#9acd32">
  <th align="left">Title</th>
  <th align="left">Artist</th>
</tr>
<xsl:for-each select="catalog/cd">
<tr>
  <td><xsl:value-of select="title"/></td>
  <td><xsl:value-of select="artist"/></td>
</tr>
</xsl:for-each>
</table>
</body> </html>
</xsl:template>
</xsl:stylesheet>

  <cd>
    <title>Hide your heart</title>
    <artist>Bonnie Tyler</artist>
    <country>UK</country>
    <company>CBS Records</company>
    <price>9.90</price>
    <year>1988</year>
  </cd>
...
XML is a metalanguage that allows users to define markup. XML separates content and structure from formatting. XML is the de facto standard to represent and exchange structured information on the Web. XML is supported by query languages.
The nesting of tags does not have standard meaning.
The semantics of XML documents is not accessible to machines, only to people.
Collaboration and exchange are supported if there is underlying shared understanding of the vocabulary.
XML is well-suited for close collaboration, where domain- or community-based vocabularies are used.
- It is less well-suited for global communication.
