CMSC 341

Asymptotic Analysis
Complexity

How many resources will it take to solve a problem of a given size?
  – time
  – space

Expressed as a function of problem size (beyond some minimum size)
  – how do requirements grow as size grows?

Problem size
  – number of elements to be handled
  – size of thing to be operated on
Mileage Example

Problem:
John drives his car, how much gas does he use?
The Goal of Asymptotic Analysis

How to analyze the running time (aka computational complexity) of an algorithm in a theoretical model. Using a theoretical model allows us to ignore the effects of

– Which computer are we using?
– How good is our compiler at optimization

We define the running time of an algorithm with input size n as $T(n)$ and examine the rate of growth of $T(n)$ as n grows larger and larger and larger.
Growth Functions

Constant

\[ T(n) = c \]

ex: getting array element at known location
    trying on a shirt
    calling a friend for fashion advice

Linear

\[ T(n) = cn \ [\text{+ possible lower order terms}] \]

ex: finding particular element in array (sequential search)
    trying on all your shirts
    calling all your n friends for fashion advice
Growth Functions (cont)

Quadratic

T(n) = cn^2 [ + possible lower order terms]

ex: sorting all the elements in an array (using bubble sort)
    trying all your shirts (n) with all your ties (n)
    having conference calls with each pair of n friends

Polynomial

T(n) = cn^k [ + possible lower order terms]

ex: looking for maximum substrings in array
    trying on all combinations of k separates types of
    apparels (n of each)
    having conferences calls with each k-tuple of n friends
Growth Functions (cont)

Exponential

\[ T(n) = c^n \text{ [ + possible lower order terms]} \]

ex: constructing all possible orders of array elements

Logarithmic

\[ T(n) = \lg n \text{ [ + possible lower order terms]} \]

ex: finding a particular array element (binary search) trying on all Garanimal combinations getting fashion advice from n friends using phone tree
A graph of Growth Functions

T(n)

Problem Size, n

\[
\begin{align*}
\text{lg(n)} & \quad \text{n lg(n)} & \quad n^3 \\
n & \quad n^2 & \quad 2^n
\end{align*}
\]
Asymptotic Analysis

What happens as problem size grows really, really large? (in the limit)

– constants don’t matter
– lower order terms don’t matter
Analysis Cases

What particular input (of given size) gives worst/best/average complexity?

**Best Case:** if there’s a permutation of input data that minimizes “run time efficiency”, then that minimum is the best case run time efficiency. **Worst Case** is defined by replacing “minimizes” by “maximizes”.

Mileage example: how much gas does it take to go 20 miles?

- **Worst case:** all uphill
- **Best case:** all downhill, just coast
- **Average case:** “average terrain”
Cases Example

Consider sequential search on an unsorted array of length $n$, what is time complexity?

Best case:

Worst case:

Average case:
Definition of Big-Oh

\[ T(n) = O(f(n)) \] (read “\( T(n) \) is Big-Oh of \( f(n) \)”)

if and only if

\[ T(n) \leq cf(n) \] for some constants \( c, n_0 \) and \( n \geq n_0 \)

This means that eventually (when \( n \geq n_0 \)), \( T(n) \) is always less than or equal to \( c \) times \( f(n) \).

Loosely speaking, \( f(n) \) is an “upper bound” for \( T(n) \).
Big-Oh Example

Suppose we have an algorithm that reads N integers from a file and does something with each integer.

The algorithm takes some constant amount of time for initialization (say 500 time units) and some constant amount of time to process each data element (say 10 time units).

For this algorithm, we can say $T(N) = 500 + 10N$.

The following graph shows $T(N)$ plotted against $N$, the problem size and 20N.

Note that the function $N$ will never be larger than the function $T(N)$, no matter how large $N$ gets. But there are constants $c_0$ and $n_0$ such that $T(N) \leq c_0N$ when $N \geq n_0$, namely $c_0 = 20$ and $n_0 = 50$.

Therefore, we can say that $T(N)$ is in $O(N)$.
$T(N)$ vs. $N$ vs. $20N$
Simplifying Rules

1. If \( f(n) = O(g(n)) \) and \( g(n) = O(h(n)) \), then \( f(n) = O(h(n)) \)

2. If \( f(n) = O(kg(n)) \) for any \( k > 0 \), then \( f(n) = O(g(n)) \)

3. If \( f_1(n) = O(g_1(n)) \) and \( f_2(n) = O(g_2(n)) \),
   then \( f_1(n) + f_2(n) = O(\max (g_1(n), g_2(n))) \)

4. If \( f_1(n) = O(g_1(n)) \) and \( f_2(n) = O(g_2(n)) \),
   then \( f_1(n) \times f_2(n) = O(g_1(n) \times g_2(n)) \)

We will prove a number of these rules by applying the definition of Big O
Constants in Bounds

Theorem:

\[ O(cf(x)) = O(f(x)) \] (Simplifying Rule #2)

Proof:

- \( T(x) = O(cf(x)) \) implies that there are constants \( c_0 \) and \( n_0 \) such that \( T(x) \leq c_0(cf(x)) \) when \( x \geq n_0 \)
- Therefore, \( T(x) \leq c_1(f(x)) \) when \( x \geq n_0 \) where \( c_1 = c_0c \)
- Therefore, \( T(x) = O(f(x)) \)
Sum in Bounds

Theorem: (Simplifying Rule 3)

Let \( T_1(n) = O(f(n)) \) and \( T_2(n) = O(g(n)) \).

Then \( T_1(n) + T_2(n) = O(\max (f(n), g(n))) \).

Proof:

- From the definition of \( O \), \( T_1(n) \leq c_1 f(n) \) for \( n \geq n_1 \) and \( T_2(n) \leq c_2 g(n) \) for \( n \geq n_2 \).
- Let \( n_0 = \max(n_1, n_2) \).
- Then, for \( n \geq n_0 \), \( T_1(n) + T_2(n) \leq c_1 f(n) + c_2 g(n) \).
- Let \( c_3 = \max(c_1, c_2) \).
- Then, \( T_1(n) + T_2(n) \leq c_3 f(n) + c_3 g(n) \)
  \( \leq 2c_3 \max(f(n), g(n)) \)
  \( \leq c \max(f(n), g(n)) \)
  \( = O(\max(f(n), g(n))) \)
Products in Bounds

Theorem: (Simplifying Rule 4)
Let $T_1(n) = O(f(n))$ and $T_2(n) = O(g(n))$.
Then $T_1(n) \times T_2(n) = O(f(n) \times g(n))$.

Proof:
- Since $T_1(n) = O(f(n))$, then $T_1(n) \leq c_1 f(n)$ when $n \geq n_1$
- Since $T_2(n) = O(g(n))$, then $T_2(n) \leq c_2 g(n)$ when $n \geq n_2$
- Hence $T_1(n) \times T_2(n) \leq c_1 c_2 f(n) \times g(n)$ when $n \geq n_0$
  where $n_0 = \max(n_1, n_2)$
- And $T_1(n) \times T_2(n) \leq c \times f(n) \times g(n)$ when $n \geq n_0$
  where $n_0 = \max(n_1, n_2)$ and $c = c_1 c_2$
- Therefore, by definition, $T_1(n) \times T_2(n) = O(f(n) \times g(n))$.
Polynomials in Bounds

Theorem:
If $T(n)$ is a polynomial of degree $x$, then $T(n) = O(n^x)$.

Proof:

- $T(n) = n^x + n^{x-1} + \ldots + k$ is a polynomial of degree $x$.
- By the sum rule, the largest term dominates.
- Therefore, $T(n) = O(n^x)$.
Example

Code:

\[
a = b;
\]

Complexity:
Example

Code:

```c
sum = 0;
for (i = 1; i <= n; i++)
    sum += n;
```

Complexity:
Example

Code:

```c
sum1 = 0;
for (i = 1; i <= n; i++)
    for (j = 1; j <= n; j++)
        sum1++;
```

Complexity:
Example

Code:

\[
\text{sum2} = 0;
\]

\[
\text{for } (i = 1 ; i <= n; i++)
\]

\[
\text{for } (j = 1; j <= i; j++)
\]

\[
\text{sum2}++; 
\]

Complexity:
Example

Code:

```c
sum = 0;
for (j = 1; j <= n; j++)
    for (i = 1; i <= j; i++)
        sum++;
for (k = 0; k < n; k++)
    A[k] = k;
```

Complexity:
Example

Code:

```c
sum1 = 0;
for (k = 1; k <= n; k *= 2)
    for (j = 1; j <= n; j++)
        sum1++;
```

Complexity:
Example

Code:

```c
sum2 = 0;
for (k = 1; k <= n; k *= 2)
    for (j = 1; j <= k; j++)
        sum2++;
```

Complexity:
Example

• Square each element of an N x N matrix

• Printing the first and last row of an N x N matrix

• Finding the smallest element in a sorted array of N integers

• Printing all permutations of N distinct elements
Some Questions

1. Is upper bound the same as worst case?

2. What if there are multiple parameters?

   Ex: Rank order of p pixels in c colors

   ```
   for (i = 0; i < c; i++)
       count[i] = 0;
   for (i = 0; i < p; i++)
       count[value(i)]++;
   sort(count)
   ```
Space Complexity

Does it matter?

What determines space complexity?

How can you reduce it?

What tradeoffs are involved?
A General Theorem

Consider the limit of 2 functions, \( f(x) \) and \( g(x) \) as \( x \) grows large:

\[
l = \lim_{x \to \infty} f(x)/g(x)
\]

\( l \) can go only to \( 0, \infty \), or some constant.

If \( l = 0 \), then \( f(x) \) is \( O(g(x)) \)

If \( l = \infty \) then \( g(x) \) is \( O(f(x)) \)

\( l \) = some constant if and only if \( f(x)/g(x) \) is \( O(1) \).

Example: \( f(x) = x^2 \) and \( g(x) = x^3 \) Then \( l = \lim_{x \to \infty} x^2/x^3 = 0 \) and \( x^2 \) is \( O(x^3) \)
L’Hôpital’s Rule

Frequently, when we try to use the general theorem, we get an indeterminate form of $\infty/\infty$. In that case, we can use *L’Hôpital’s rule*, which states that

$$\lim_{x \to \infty} \frac{f(x)}{g(x)} = \lim_{x \to \infty} \frac{f'(x)}{g'(x)}$$

We can use this rule to apply the General Theorem. The next slide is an example.
Polynomials of Logarithms in Bounds

Theorem:
\[ \lg^k n = O(n) \] for any positive constant \( k \)

Proof:
- Note that \( \lg^k n \) means \( (\lg n)^k \).
- Need to show \( \lg^k n \leq cn \) for \( n \geq n_0 \). Equivalently, can show \( \lg n \leq cn^{1/k} \)
- Letting \( a = 1/k \), we will show that \( \lg n = O(n^a) \) for any positive constant \( a \). Use L’Hospital’s rule:

\[
\lim_{n \to \infty} \frac{\lg n}{cn^a} = \lim_{n \to \infty} \frac{\lg e}{acn^{a-1}} = \lim_{n \to \infty} \frac{c_2}{n^a} = 0
\]

Ex: \( \lg^{1000000}(n) = O(n) \)
Polynomials vs Exponentials in Bounds

Theorem:
\[ n^k = O(a^n) \text{ for } a > 1 \]

Proof:

- Use L’Hospital’s rule

\[
\lim_{n \to \infty} \frac{n^k}{a^n} = \lim_{n \to \infty} \frac{kn^{k-1}}{a^n \ln a}
\]

\[
= \lim_{n \to \infty} \frac{k(k-1)n^{k-2}}{a^n \ln^2 a}
\]

\[
= \lim_{n \to \infty} \frac{k(k-1)\cdots1}{a^n \ln^k a}
= 0
\]

Ex: \[ n^{1000000} = O(1.00000001^n) \]

Big-Oh is not the whole story

Suppose you have a choice of two approaches to writing a program. Both approaches have the same asymptotic performance (for example, both are $O(n \lg(n))$. Why select one over the other, they're both the same, right? They may not be the same. There is this small matter of the constant of proportionality.

Suppose algorithms A and B have the same asymptotic performance, $T_A(n) = T_B(n) = O(g(n))$. Now suppose that A does 10 operations for each data item, but algorithm B only does 3. It is reasonable to expect B to be faster than A even though both have the same asymptotic performance. The reason is that asymptotic analysis ignores constants of proportionality.

The following slides show a specific example.
Algorithm A

Let's say that algorithm A is

{ 
    initialization // takes 50 units
    read in n elements into array A; // 3 units per element
    for (i = 0; i < n; i++)
    {
        do operation1 on A[i]; // takes 10 units
        do operation2 on A[i]; // takes 5 units
        do operation3 on A[i]; // takes 15 units
    } 
}

\[ T_A(n) = 50 + 3n + (10 + 5 + 15)n = 50 + 33n \]
Algorithm B

Let's now say that algorithm B is

\{
    initialization \quad // takes 200 units
    read in n elements into array A; \quad // 3 units per element
    for (i = 0; i < n; i++)
      \{
        do operation1 on A[i]; \quad // takes 10 units
        do operation2 on A[i]; \quad // takes 5 units
      \}
\}

\[ T_B(n) = 200 + 3n + (10 + 5)n = 200 + 18n \]
$T_A(n)$ vs. $T_B(n)$

![Graph showing the comparison between $T_A(n)$ and $T_B(n)$, with two lines: one for $50 + 33n$ (red) and another for $200 + 18n$ (green).]
A concrete example

The following table shows how long it would take to perform $T(n)$ steps on a computer that does 1 billion steps/second. Note that a microsecond is a millionth of a second and a millisecond is a thousandth of a second.

<table>
<thead>
<tr>
<th>N</th>
<th>$T(n) = n$</th>
<th>$T(n) = n\log n$</th>
<th>$T(n) = n^2$</th>
<th>$T(n) = n^3$</th>
<th>$T_{n} = 2^n$</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>0.005 microsec</td>
<td>0.01 microsec</td>
<td>0.03 microsec</td>
<td>0.13 microsec</td>
<td>0.03 microsec</td>
</tr>
<tr>
<td>10</td>
<td>0.01 microsec</td>
<td>0.03 microsec</td>
<td>0.1 microsec</td>
<td>1 microsec</td>
<td>1 microsec</td>
</tr>
<tr>
<td>20</td>
<td>0.02 microsec</td>
<td>0.09 microsec</td>
<td>0.4 microsec</td>
<td>8 microsec</td>
<td>1 millise cond</td>
</tr>
<tr>
<td>50</td>
<td>0.05 microsec</td>
<td>0.28 microsec</td>
<td>2.5 microsec</td>
<td>125 microsec</td>
<td>13 days</td>
</tr>
<tr>
<td>100</td>
<td>0.1 microsec</td>
<td>0.66 microsec</td>
<td>10 microsec</td>
<td>1 millisecond</td>
<td>$4 \times 10^{13}$ years</td>
</tr>
</tbody>
</table>

Notice that when $n \geq 50$, the computation time for $T(n) = 2^n$ has started to become too large to be practical. This is most certainly true when $n \geq 100$. Even if we were to increase the speed of the machine a million-fold, $2^n$ for $n = 100$ would be 40,000,000 years, a bit longer than you might want to wait for an answer.
