Intel Assembly

Format of an assembly instruction:

```
LABEL     OPCODE   OPERANDS COMMENT
DATA1     db       00001000b   ;Define DATA1 as decimal 8
START:    mov      eax, ebx    ;Copy ebx to eax
```

LABEL:

Stores a symbolic name for the memory location that it represents.

OPCODE:

The instruction itself.

OPERANDS:

A register, an immediate or a memory address holding the values on which the operation is performed.

There can be from 0 to 3 operands.

Data Addressing Modes

Data movement instructions move data (bytes, words and doublewords) between registers and between registers and memory.

Only the **movs** instruction can have both operands in memory.

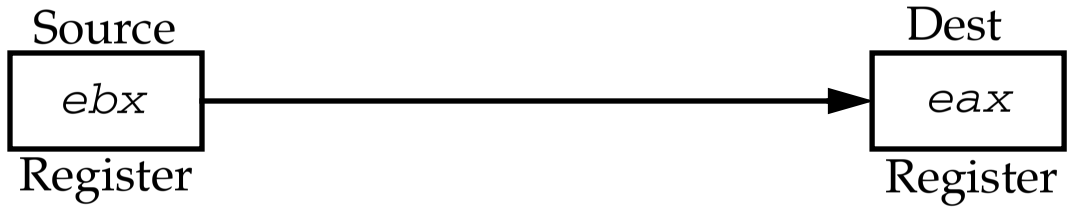
Most data transfer instructions do not change the **EFLAGS** register.

Format:

opcode *destination, source*

- Register

mov *eax, ebx*



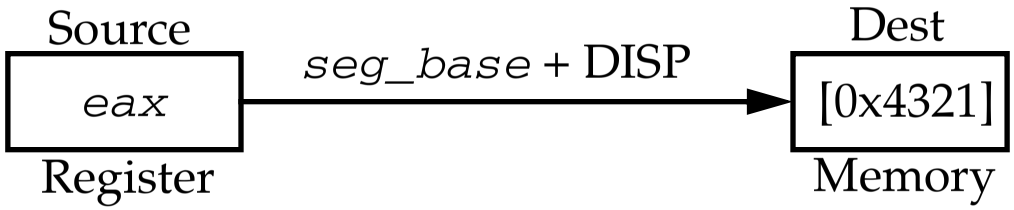
Data Addressing Modes

- Immediate

mov *ch*, 0x4b

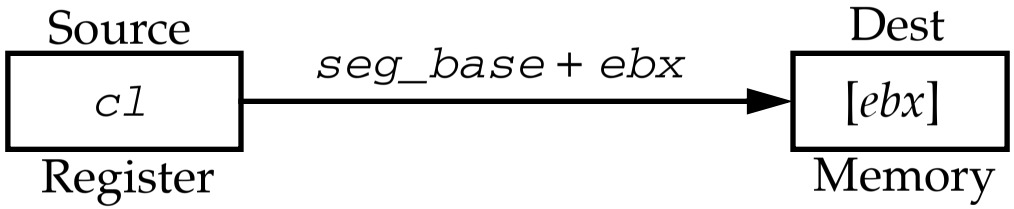
- Direct (eax), Displacement (other regs)

mov [0x4321], *eax*



- Register Indirect

mov [*ebx*], *cl*

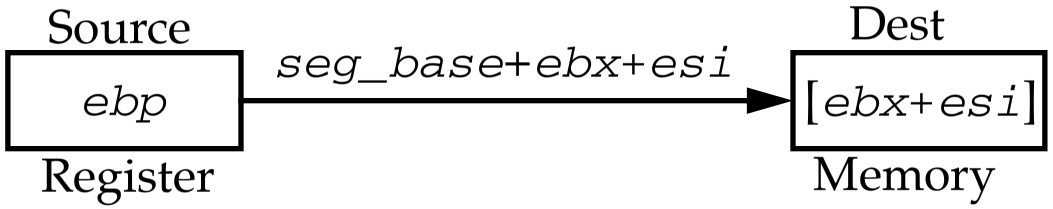


Any of *eax*, *ebx*, *ecx*, *edx*, *ebp*, *edi* or *esi* may be used.

Data Addressing Modes

- Base-plus-index

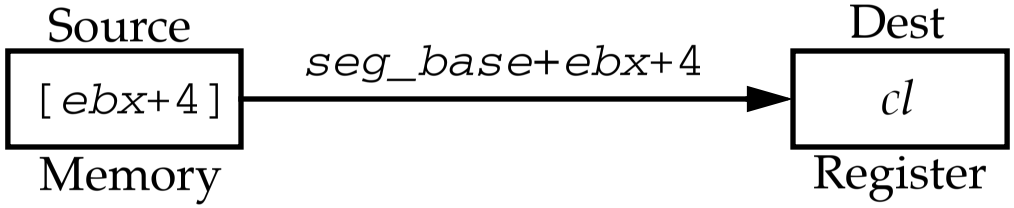
mov [*ebx+esi*], *ebp*



Any combination of *eax*, *ebx*, *ecx*, *edx*, *ebp*, *edi* or *esi*.

- Register relative

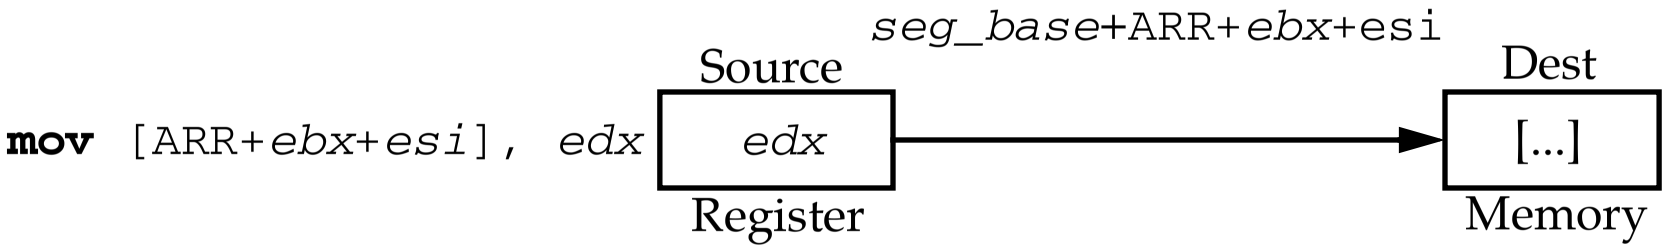
mov *cl*, [*ebx+4*]



A second variation includes: **mov** *eax*, [ARR+*ebx*]

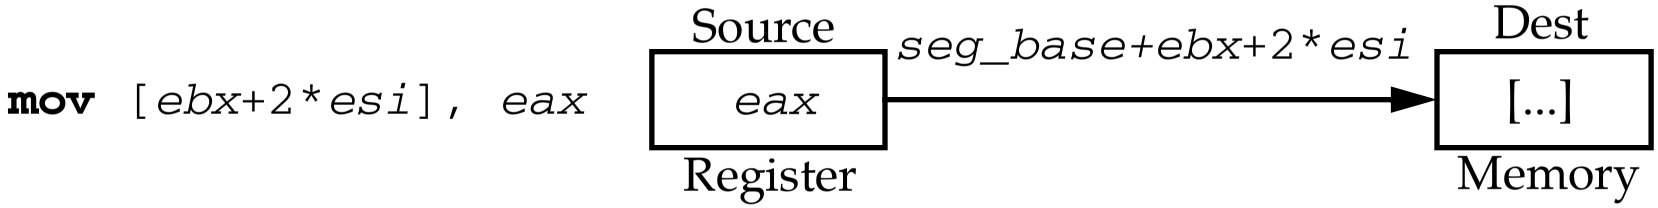
Data Addressing Modes

- Base relative-plus-index



A second variation includes: **mov** *eax*, [*ebx*+*edi*+4]

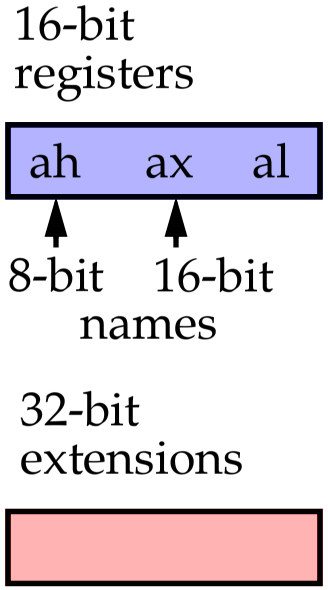
- Scaled-index

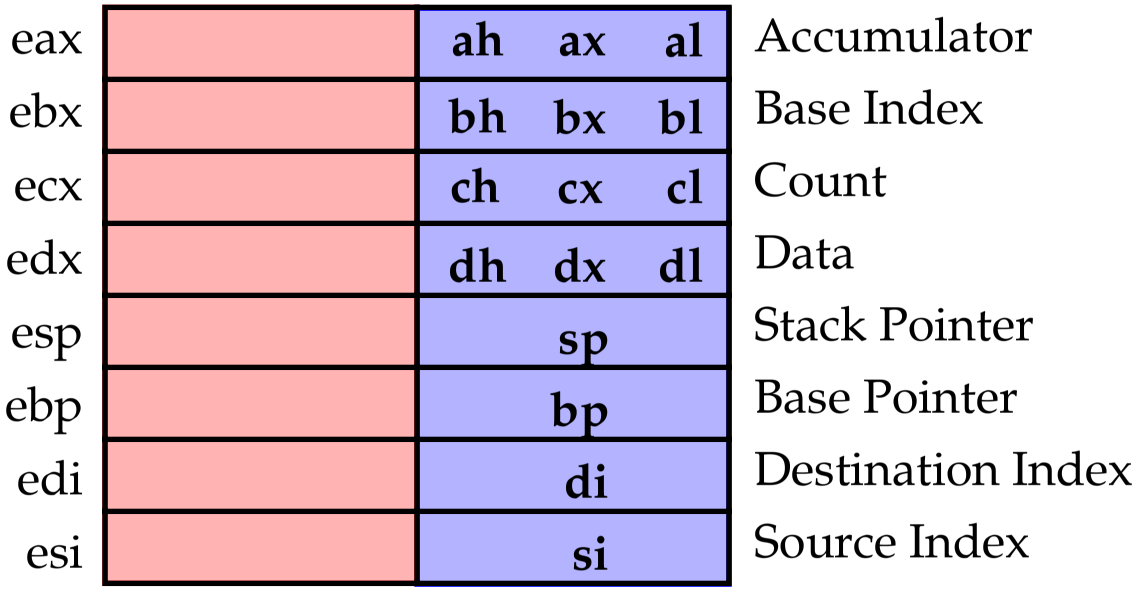


A second variation includes: **mov** *eax*, *ebx**2+*ecx*+offset
Scaling factors can be 2X, 4X or 8X.

Data Addressing Modes

Register addressing:





Note: **mov** really COPIES data from the source to destination register.

- Never mix an 16-bit register with a 32-bit, etc.

  For example

```
mov eax, bx      ;ERROR: NOT permitted.
```

- None of the **mov** instruction effect the EFLAGS register.

Data Addressing Modes

Immediate addressing:

The value of the operand is given as a constant in the instruction stream.

```
mov eax, 0x12345
```

- Use **b** for binary, **q** for octal and nothing for decimal.
- ASCII data requires a set of apostrophes:

```
mov eax, 'A'    ;Moves ASCII value 0x41 into eax.
```

Register and immediate addressing example:

```
        global main
        section .text   ;start of the code segment.
main:
        mov eax, 0      ;Immediate addressing.
        mov ebx, 0x0000
        mov ecx, 0
        mov esi, eax    ;Register addressing.
        ...
```

Data Addressing Modes

Direct addressing:

Transfers between memory and *al*, *ax* and *eax*.

Usually encoded in 3 bytes, sometime 4:

```
mov al, DATA1          ;Copies a byte from DATA1.
mov al, [0x4321]       ;Some assemblers don't allow this.
mov al, ds:[0x1234]
mov DATA2, ax          ;Copies a word to DATA2.
```

Displacement:

```
mov cl, DATA1          ;Copies a byte from DATA1.
mov edi, SUM           ;Copies a doubleword from SUM.
```

Displacement instructions are encoded with up to 7 bytes (32 bit register and a 32 bit displacement).

Data Addressing Modes

Direct and displacement addressing example:

```
                        global main
0000                    section .data
0000 10         DATA1   db      0x10
0001 00         DATA2   db      0

0000                    section .text
                main:
0017 A0 0000 R          mov al, DATA1
001A 8B 1E 0001 R       mov bx, DATA2
```

Note: Direct addressing (using **al**) requires 3 bytes to encode while Displacement (using **bx**) requires 4.

Register Indirect addressing:

Offset stored in a register is added to the segment register.

```
mov ecx, [ebx]
mov [edi], [ebx]
```

The memory to memory **mov** is allowed with string instructions.

Data Addressing Modes

Register Indirect addressing (cont)

Any register EXCEPT **esp** for the 80386 and up.

For **eax**, **ebx**, **ecx**, **edx**, **edi** and **esi**: The data segment is the default.

For **ebp**: The stack segment is the default.

Some versions of register indirect require special assembler directives *byte*, *word*, or *dword*

```
mov al, [edi]      ;Clearly a byte-sized move.
mov [edi], 0x10    ;Ambiguous.
```

Does [*edi*] address a byte, a word or a double-word?

The assembler can't determine the size of 0x10 !

Use:

```
mov byte [edi], 0x10     ;A byte transfer.
```
